

This sequence diagram was generated with EventStudio System Designer (<http://www.EventHelix.com/EventStudio>).

TCP (Transmission Control Protocol) provides a reliable end to end service that delivers packets over the Internet. Packets are delivered in sequence without loss or duplication.

This sequence diagram explores following: (1) The three-way handshake to establish a TCP (2) Data transfer using the byte oriented sequence numbers (3) Release of a TCP connection.

The TCP socket creation and deletion on the server and client is also covered.

Client application sends 1024 bytes of data to the socket

This TCP connection limits TCP segments to 512 bytes, thus the received data is split into 2 TCP segments

The first TCP segment is sent with a sequence number of 1. This is the sequence number for the first byte in the segment. (Note that unlike other protocols, TCP maintains sequence numbers at byte level. The sequence number field in the TCP header corresponds to the first byte in the segment.)

Bytes in the first TCP segment correspond to 1 to 512 sequence numbers. Thus, the second TCP segment contains data starting with 513 sequence number

Client has received both the TCP segments

Socket passes data to Client application

Client sends a TCP ACK with the next expected sequence number set to 701

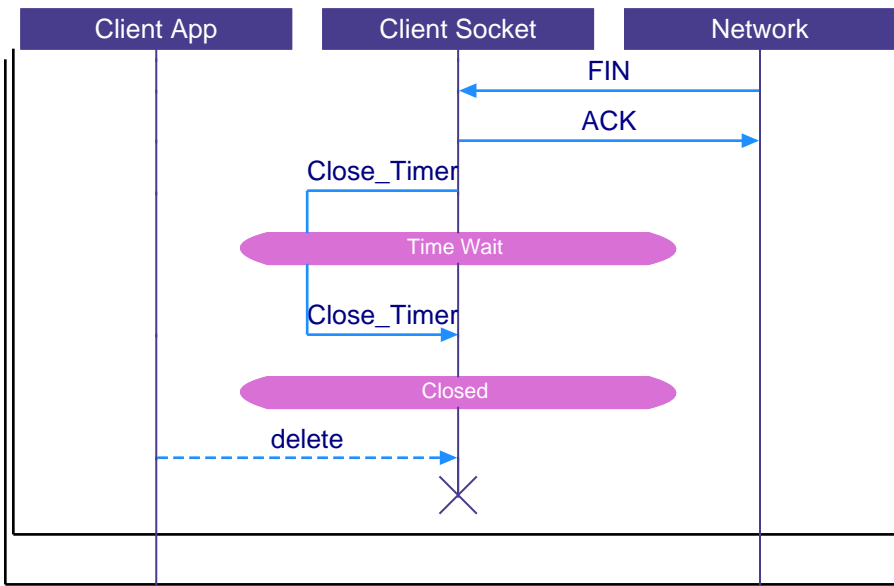

Client application wishes to release the TCP connection

Client sends a TCP segment with the FIN bit set in the TCP header

Client changes state to FIN Wait 1 state

Client receives the ACK

Client changes state to FIN Wait 2. In this state, the TCP connection from the client to server is closed. Client now waits close of TCP connection from the server end

Client receives FIN

Client sends ACK

Client starts a timer to handle scenarios where the last ack has been lost and server resends FIN

Client waits in Time Wait state to handle a FIN retry

Close timer has expired. Thus the client end connection can be closed too.
